Asian populations including Koreans are assumed to have a higher isoflavone intake due to the higher consumption of soybean. However, it is difficult to estimate isoflavone intake because there is no isoflavone database in Korea. In this study, an isoflavone database was established with systematic review. Literature with analytical values of Korean soybeans and its products were collected and evaluated to establish an isoflavone database. A total of 142 food items containing isoflavones were selected among 2,932 food items in the Korean Nutrient Database. Among these, only 25 food items were evaluated with analytical values and the remaining 98 items were replaced with adaptations or calculations from similar items. Dietary intake of isoflavones was assessed for 426 boys and 365 girls aged 8 to 11 years with 3-day food records. The daily mean isoflavone intake was 8.3 mg among boys and 7.2 mg among girls. More than 70% of subjects had a daily isoflavone intake below 10 mg. The most contributory food item to the isoflavone intake among adolescents was tofu in quantity and soybean sauce in frequency. This database could be used to estimate isoflavone intakes from dietary data among various populations and to evaluate the relationships between isoflavone intake and chronic disease.

Key Words: isoflavone database, isoflavone intake, evaluation, children, Korea

Introduction
Recently more attention has been paid to isoflavones in epidemiological and clinical studies.¹ Isoflavones, a type of flavonoids, are found mostly in soybeans. Clinical studies found that a high intake of isoflavones increase bone mineral content among middle-aged women,² and protect against a decline in bone density.³ Recent studies showed that soybean products with high contents of isoflavones decrease LDL oxidation in hyperlipidemic population,⁴ and that Asian women who have a high intake of soybeans foods had a lower risk of breast cancer,⁵ indicating that isoflavone intake might have positive effects on health.

A nutrient database containing isoflavones was developed in the USA.⁷ This isoflavone database was developed with careful evaluation of items and using a confidence code, which enables researchers to better understand the database and which improves its validity. Continuous updates of isoflavone databases are necessary to keep them reliable, due to the interest in new components, new skills of plant breeding, and the rapid increase of processed foods with added isoflavones.⁷

Koreans have traditionally consumed significant quantity of soybeans and their products. However, the consumption of soybean products among adolescents has decreased. According to the 1998 National Health and Nutrition Survey,⁸ the average daily intake of soybeans and their products among 7-12 year old children was 23.7 g. However, a survey conducted in 2001¹⁰ showed a decrease to 18.8 g, which would indicate a rapid decrease in isoflavone intake and concerns about the possible consequences on health.

To date there is no isoflavone database in Korea. A few studies about isoflavones have been conducted to analyze isoflavone content for a limited number of food items¹¹-¹³ and to evaluate their clinical effects. Because there is no standard database to estimate isoflavone intakes, there have been problems regarding study comparisons. In addition, most studies have been conducted among adults and only a few have been conducted among children, especially around puberty.

The purpose of this study was to establish an isoflavone database for usual Korean foods based on a systematic review of published data and to evaluate the intake of isoflavones among Korean children.

Materials and methods

Preparation of a Korean Isoflavone Database

A total of 142 food items were selected among 2,932 food items in the Korean Nutrient Database, because only those items were assumed to contain isoflavones. Since vegetables contain only small amounts of isoflavones, their isoflavone contents were assumed to be zero. The major food sources of isoflavones are soybeans and their products.

The isoflavone database was jointly developed by USDA and Iowa State University in the U.S. with systematic evaluation. However, there were only a few Asian food items. We reviewed all national and international articles published between January 1990 and March 2004, which analyzed the isoflavone contents of Korean foods, especially soybeans and their products. Among them 22 articles were selected which included analytical values of isoflavone contents. Although we tried to contact authors with queries, 6 articles were excluded because of insufficient information or inappropriate sampling.

Data for only the most common isoflavones, daidzein, genistein, and glycitein were evaluated using the expert systematic evaluation system that USDA also used for the establishment of the isoflavone database. This evaluation system includes five general categories, namely analytical methods, analytical quality control, number of samples, sample handling, and sampling plan. Each analytical value of isoflavones in a food item from each reference was rated from 0 to 3 with specific criteria for each category. Specific details of the evaluation system were described by Mangeles et al. Each analytical value of isoflavone in certain food items receives a score between 0 to 3 points for the five categories and the average points result in a ‘Quality Index’. The sum of these ‘Quality Indexes’ of a food item, which excludes points below 1, is called the ‘Quality Sum’ based on which the food item is assigned a letter between A (considerable confidence) and C (less confidence) as a ‘Confidence Code’. Table 1 provides an example of ratings assigned to various references for isoflavone in a Korean soymilk.

Regarding Korean soymilk we found 6 published articles and reviewed their analytical values of isoflavones with 5 categories of the expert evaluation system. The average score with 5 categories from 6 reference articles resulted in the quality index. Among the 6 references, analytic values from 3 references were below 1.0 point so they were excluded from further evaluation. Quality indexes, 1, 1.2 and 2.4 from 3 reference articles amounted to the quality sum of 4.6. If the quality sum is more than 3.4 and less than 6.0 point, the confidence code is “B”. In addition, median values were selected in this study because the distribution of analytical values of isoflavone was not normal and the variance was too high. Therefore, the isoflavone content for Korean soymilk was 9.02 mg /100g with a confidence code B.

The analytical values of only 25 food items from the total of 142 food items were evaluated with confidence codes. The analytical values of isoflavones in 98 food items were unreliable or not available from reviewed literatures even though the food is assumed to contain isoflavones. The values of isoflavones in these food items were assigned either by calculation or adaptation from isoflavone values of similar food items. For 19 food items, USDA database were used.

Evaluation of Isoflavone Intake

A total of 791 subjects (426 boys and 365 girls), aged between 8 and 11 years, were recruited from two elementary schools in Seoul, Korea for this study. The 3-day food record method was used to assess the dietary intake with one day on the weekend and two weekdays. Trained staff taught subjects how to keep food records at the first visit. When dietary data were collected on the second visit after 1 week, trained staff reviewed incomplete food records. The study protocol was reviewed and approved by the Institutional Review Board of Seoul National University.

The nutrient intake was calculated based on the Korean Nutrient Database and isoflavone intake was calculated with the database established in this study. The correlation between isoflavone and other nutrient intakes were analyzed. Adjusted for energy intake, isoflavone density (isoflavone intake per 1,000kcal) was calculated and correlated with other nutrients. Food items, which contribute to the isoflavone intakes, were ranked according to amount and frequency of intake.

Statistical Analysis

Statistical analysis was performed using the Statistical Analysis System (SAS version 8.01, SAS Institute, Cary, NC).

Results

Structure of the isoflavone database for usual Korean foods

The isoflavone database was established for usual Korean foods. Among 2,932 food items in Korean Nutrient Database, 2,790 food items were assumed to have no isoflavone, which were assigned the estimated value of 0. Among the remaining 142 food items, only 25 food items had been evaluated with analytical values using the systematic evaluation system with which USDA has also used. The isoflavone contents of 19 food items were used from the USDA isoflavone database and the isoflavone contents of 98 food items were calculated or adapted from similar food items (Table 2).

Evaluation of analytical values of isoflavone

Table 3 shows the isoflavone contents of 25 food items with confidence code from the expert evaluation system and total isoflavone contents. Only yellow soybean (dried, domestic) was assigned an ‘A’ confidence code, 8 food items were assigned a ‘B’ code and the remaining 16 food items were assigned a ‘C’.

Table 4 shows the isoflavone contents for usual Korea foods with the moisture content and most common

isoflavones established in this study. The total isoflavone contents are the sum of daidzein, genistein and glycitein. If the food items did not contain glycitein, only daidzein and genistein contributed to the total isoflavone contents. The moisture contents of food items were obtained from the Korean Nutrient Database and used when calculated to convert from dry-weight value to wet-weight value of isoflavone for food items. The type of source was classified with “A” for analytical values, “U” for adaptation from USDA database, and “S” for adaptation from similar foods.

**Evaluation of isoflavone intake and nutrient intake**

Dietary intake of isoflavones was calculated with data from 791 elementary school students (54% boys and 46% girls). The mean age of students was 9.8 years, and did not differ significantly between genders. The average daily isoflavone intake was 8.3 mg among boys and 7.2 mg among girls in this study. Eighty-three percent of girls and 71% of boys had an isoflavone intake between 0mg to 10mg (Fig 1). More than half of all girls had an isoflavone intake between 2.5mg and 7.5mg. The intake range was 0.002-43.14 mg among girls and 1.8-40.6 mg among boys and the distribution of isoflavone intake was skewed to the left.

Source type (A from analytic value; U from USDA database; S from adaptation of similar foods)
Figure 1(b) shows that the isoflavone density is below 6mg/1000kcal among 74% of girls and among 81% of boys. Boys had a higher isoflavone intake, but the isoflavone density was higher among girls. The distribution of isoflavone density was also skewed to the left.

The correlation between isoflavone density and other nutrients are presented in Table 5. Among boys, calcium, phosphorous, sodium, folate and vitamin E had a significantly positive correlation with isoflavone density, and fat, vitamin B₁, vitamin B₂ and retinol had a significantly negative correlation. Among girls, protein, calcium, phosphorous, iron, sodium, vitamin C and folate had positive correlation and fat had significantly negative correlations with isoflavone density.

Table 6 presents the 10 major food items that contributed to the isoflavone intake by amount and frequency of consumption. Tofu (soybean curd) was the main food item, which contributed to the isoflavone intake in amount among girls and boys. Soybean sauce and red pepper paste were the highest in frequency, and are also two of the most frequently used seasonings by Koreans.

There was no difference in food sources for isoflavone intake between boys and girls.

Discussion
The isoflavone database for usual Korean foods was established and used to estimate isoflavone intake for Korean adolescents. Because Korean Nutrient Database does not contain isoflavone contents, previous studies among Koreans were not able to assess isoflavone intakes.

In this study the isoflavone database was established using the critical evaluation system, which was also used to establish the USDA-isoflavone database. From available published articles the analytical values of isoflavone contents for Korean Nutrient Database (continued)

Source type (A from analytic value; U from USDA database; S from adaptation of similar foods)
from 25 Korean food items were reviewed. Even though isoflavone contents for each food item presented in this study are the best estimates, there are limitations and considerations. Only one item among the 25 food items (4%) had an “A” confidence code and it was quite low compared to 9% of foods in carotenoids15 and 25% in selenium16 and 9% in copper 17 database that had confidence codes of “A” with same evaluation system. One reason that this study had a low percent of foods with “A” confidence code was the difficulty to evaluate one of the five categories of the evaluation system, namely analytical method. Isoflavone exists in glucoside forms in food and is converted to the free form (aglycone) for absorption by the body.24 To analyze isoflavone contents, isoflavone glycoside in foods are broken down to aglycone by acidic hydrolysis, and loss occurs. Few articles were found to suggest an explanation for how to correct the loss due to breakdown, or how to assess the recovery rate. TheUSDA7 faced similar difficulties, while reviewing and evaluating articles when they established the isoflavone database. As a result, many food items received 0 points for the evaluation category ‘analytical method’, so that these food items were assigned a confidence code ‘C’.

In addition, several calculations were performed with published data to establish the isoflavone database in this study. If analytical values of isoflavone were presented as glycoside forms in published articles, we converted the values for glycoside forms into aglycone forms by using appropriate ratios of molecular weights regarding respective common isoflavones. If analytical values of isoflavone were presented on a dry weight basis, we converted the values to wet weight basis either by using given moisture contents or by obtaining the moisture contents from the Korean Nutrition Database.14

Another consideration was that the variety, the crop year, and the location affect the isoflavone contents of the soybeans25 and these factors contribute to the large variability in the isoflavone contents of soybeans and their

Isoflavone database and intake for Korean children

products. Choi and colleagues reported that the total isoflavone contents varied greatly in the range of 45-230mg/100g for Korean soybeans with different type of seeds. Various soybeans come out throughout the market in Korea. In this study, four varieties of soybeans were collected that contributed 97% of total soybeans supplied in Korea during the year of 2001-2003. The type of soybean as well as the product amounts was considered when calculating the isoflavone contents in this study. This resulted in the isoflavone content for yellow soybean of, 98.6mg/100g, which is different from the amount for Korean soybean in USDA database (144.99mg/100g), because the USDA reviewed only one reference article.

When starting to review the analytical values for foods, we did not aggregate similar foods because we wanted to insert the isoflavone contents into the Korean Nutrient Database, and thus we used the food item from the Korean Nutrient Database. Although an isoflavone database has been completed with a small data set, this is the first isoflavone database for usual Korean food items. It provides an important data to study isoflavone and its health effects.

We evaluated the isoflavone intake among Korean children and it was lower than that of Korean middle-aged women (24mg) and menopausal women (27mg). Other studies conducted among Asian populations with a high intake of soybeans, such as Chinese or Japanese women reported between 15 to 40 mg of isoflavone intake, which is higher than the results of this study. However, studies conducted among Caucasian middle-aged women showed an isoflavone intake of 0.2-5mg, which is lower than results of this study. African American women aged 42 to 52 had lower isoflavone intakes than Caucasians, Chinese and Japanese. These data show that the isoflavone intake differs by ethnicity, and most isoflavone studies were conducted for adults, especially women around menopause.

According to the 2001 Korean National Health and Nutrition Survey, intake from soy and its products was 19g/day for 7-12 year old adolescents compared to about 35g for adults above 30. Among studies conducted for Koreans, isoflavone intakes were 17mg/day for college women, compared to 24mg for middle-aged women. There were no available data for children and adolescents except our data (7-8mg for 8-11 years old). These data support that isoflavone intake is different between age groups, and that children have lower isoflavone intake than adults.

In this study, 71% of boys and 83% of girls had an isoflavone intake below 10mg. More than half of all girls had isoflavone intakes between 2.5 and 7.5mg. The range of intake was 0.002mg to 43mg among girls and 1.8 to 41mg among boys, which is narrower than a study among Korean middle-aged women with a range of 0 to 144mg, and is similar to Chinese women (aged 19 to 86) with a range between 5 to 33mg. In this study, distribution of isoflavone intake was skewed to the left with a similar shape than other studies.

In summary, 142 food items containing isoflavone were selected from the Korean Nutrient Database. Only 25 food items were evaluated with the analytical values using the critical evaluation process. The isoflavone intake for Korean children aged 8 to 11 was lower than that of Asian adults and higher than that of Caucasian adults. Isoflavone intakes differ between age groups and ethnicity. This study provides the baseline data to estimate isoflavone intake and make further studies possible to estimate isoflavone intake and its health benefits.

建立韓國常用食品異黃酮資料庫並評估韓國兒童異黃酮的攝取量

緣於黃豆攝取量較高，亞洲族群包含韓國被認為有較高的異黃酮攝取。然而，在韓國因為沒有異黃酮的資料庫，所以難以評估異黃酮攝取量。本研究以系統回顧的方式建立異黃酮資料庫。收集並評估文獻中韓國黃豆及其製品的分析數值，以建立異黃酮的資料庫。從韓國營養素資料庫的 2932 個食物項目中選出 142 個含異黃酮食物。其中，只有 25 個食物項目有分析數值，剩下的 98 個項目是採用適當的數值替代或是計算自相似的項目。評估年齡在 8 至 11 歲的 426 名男孩及 365 名女孩，其三天食物記錄的異黃酮飲食攝取量。男孩每日平均異黃酮攝取量為 8.3mg，女孩為 7.2mg。超過 70% 的研究對象每日異黃酮攝取量低於 10mg。青少年大部分異黃酮攝取量的主要來源為豆腐，攝取頻率較多的則為醬油。此資料庫可以依擇不同族群的飲食資料，評估異黃酮的攝取量及評估異黃酮攝取量與慢性疾病之間的相關性。
