Vitamin A deficiency (VAD) is the most common cause of childhood blindness in the developing world. It is estimated that by giving adequate vitamin A, in vitamin A deficient populations, child mortality from measles can be reduced by 50%, and mortality from diarrheal disease by 40%. Overall mortality in children 6-59 months of age can be reduced by 23%. This paper reported results from a study of vitamin A status and malnutrition of the minority ethnic group of Karen hill tribe children aged 1-6 years in the north of Thailand. All children aged 1-6 years (N = 158; 83 boys, 75 girls) from the three Karen villages (Mae Hae Tai, Mae Yot, Mae Raek) of Mae Chaem district in the north of Thailand were studied. The Karen is the largest mountain ethnic minority (“hill tribe”) group in Thailand. All children were examined by a qualified medical doctor and were assessed for their vitamin A intakes using 24 hours dietary recall. Thai food composition table from Ministry of Health, Thailand were used as references. The results were compared with the Thai Recommended Dietary Allowances. Children aged 1-3 years and 4-6 years were separately analysed due to the differences in Thai Recommended Dietary Allowances between the two age groups. A whole blood of 300 μL was obtained by “fingerstick” for determination of serum vitamin A. Community or village’s vitamin A status was assessed by using Simplified Dietary Assessment (SDA) method and Helen Keller International (HKI) food frequency method. Descriptive statistics were used to analyse the data. All families of the study boys and girls had income lower than the Thailand poverty line (US $ 1,000/year). On average, 63% of children from Mae Hae Tai village, 1.5% of children from Mae Yot village and none of children from Mae Raek village had serum vitamin A <0.7 μmol/L which indicated VAD. All boys and only girls from Mae Raek village consumed vitamin A more than the Thai RDA but girls from Mae Hae Tai village and Mae Yot village consumed vitamin A less than the Thai RDA. Both boys and girls from Mae Raek village and also girls from Mae Yot village consumed vitamin A more than the Thai RDA. Using SDA and HKI methods to assess vitamin A status of the villages to see whether VAD is a village's nutritional problem, it was found that all children from the three villages were at risk of VAD. In order to improve vitamin A status of the Karen children in Mae Chaem district, recommendations were made as follow: (1) increased use of fat and oil, particularly in areas with high risk of VAD; (2) more general work with Karen communities on how children’s diets might be improved in a culturally acceptable manner, so as to bring vitamin A consumption closer to recommended allowance level.

Key Words: Nutritional status, Diet, Vitamin A, Intakes, Vitamins, Malnutrition, Karen, Children, Hill tribe, Thailand

Introduction
The body's immune system cannot function well without adequate levels of vitamin A. Lack of vitamin A damages the surfaces of the skin, eyes, and mouth, the lining of the stomach, and the respiratory system. A child with vitamin A deficiency (VAD) has more infections, which become more severe because the immune system is damaged. VAD increases the risk that children will die or become blind. It is the most common cause of childhood blindness in the developing world. It is estimated that by giving adequate vitamin A, in vitamin A deficient populations, child mortality from measles can be reduced by 50%, and mortality from diarrheal disease by 40%. Overall mortality in children 6-59 months of age can be reduced by 23%. Current World Health Organization criteria for starting a supplementation program include a survey showing that more than 20% of children have low serum retinol levels or the presence of nightblindness either in children 2-6 years of age or in women of reproductive age, particularly pregnant women; or, any two indirect indicators, such as low availability or intake of vitamin A rich foods, high infant mortality (>100), high under five mortality (>75), high prevalence of underweight/stunting/wasting, or high measles case fatality (>1%). VAD can occur for a number of reasons. There may be too little vitamin A in the foods consumed, the body may absorb too little vitamin A, or vitamin A may be rapidly used up and then not replaced in time to avoid damage.
When body stores of vitamin A are lost, blood levels fall, damaging the immune system. Later, the eyes are damaged. Infants born to women who consume too little vitamin A have low stores at birth. The breast milk of these women is also low in vitamin A. Children between the ages of 6 months and 6 years, and women especially during pregnancy and lactation, are most likely to develop vitamin A deficiency. Nightblindness is common in pregnant women. Infants and young children who are not breastfed are at very high risk. Infants and children who do not receive enough breast milk for at least 2 years are at high risk; 500 ml of breast milk provides about 45% of vitamin A requirements in the second year of life.\(^5\) Diseases, such as measles, prolonged or severe diarrhea, and other infections, reduce blood levels and stores of vitamin A. The earliest symptoms of VAD are difficult to detect, but nightblindness is a good indicator. Most communities with VAD have a local term for nightblindness. Even at an early stage and well before any physical changes in eyes can be seen, VAD damages the immune system, making children less able to fight common infections. Interventions to prevent vitamin A deficiency are needed for all children living in areas where VAD is likely. Children who have a brother or sister with eye signs of VAD are ten times more likely to have severe VAD. Mothers of these children are five to ten times more likely to have night blindness. Children from the same neighborhoods and communities as someone with VAD are twice as likely to have or develop severe VAD.\(^6\) This paper reported results from a study of vitamin A status and malnutrition of the minority ethnic group of Karen hill tribe children aged 1-6 years in the north of Thailand.

### Methodology

#### Study sites and subjects

All children aged 1-6 years (N = 158) from the three Karen villages (Mae Hae Tai, Mae Yot, Mae Raek) of Mae Chaem district were studied. Mae Chaem district is located about 160 kilometers southwest of Chiang Mai province in the north of Thailand. Chiang Mai is the second largest city in Thailand with a population of about 1.5 millions. The Karen is the largest mountain ethnic minority (“hill tribe”) group in Thailand. The study included 83 boys and 75 girls as shown in Table 1. All subject’s parents were asked to complete a socio-demographic questionnaire. This research project was approved by Chiang Mai University Human Ethic Committee, Thailand. All children's parents were requested to sign or thumb printed a consent form.

#### Assessment of vitamin A status

A whole blood of 300 μL was obtained by “fingerstick” for determination of serum vitamin A. The results were compared with the reference values by age.\(^7\) All children were assessed for their vitamin A intakes using 24 hours dietary recall. Thai food composition table from Ministry of Health were used as references.\(^8\) The results were compared with the Thai Recommended Dietary Allowances (RDA).\(^9\) Children aged 1-3 years and 4-6 years were separately analysed due to the differences in Thai Recommended Dietary Allowances (RDA) between the two age groups. Community or village’s vitamin A status was assessed by using Simplified Dietary Assessment (SDA) method, and Helen Keller International (HKI) food frequency method.\(^10\),\(^11\) They were used to assess whether or not a village has a vitamin A deficiency problem. The criteria for SDA and HKI were as follow. SDA method: Criteria: Risk index interpretation for Consumption Index (CI) & Usual Pattern of Food consumption (UPF)

<table>
<thead>
<tr>
<th>Risk</th>
<th>CI</th>
<th>UPF</th>
</tr>
</thead>
<tbody>
<tr>
<td>High risk (HR)</td>
<td>&lt;5</td>
<td>&lt;120</td>

<td>Moderate risk (MR)</td>
<td>5-7</td>
<td>120-210</td>
</tr>
<tr>
<td>Low risk (LR)</td>
<td>&gt;7</td>
<td>&gt;210</td>
</tr>
</tbody>
</table>

CI calculated from 24 hours food recall, then find the mean of the whole village. UPF calculated from food frequency questionnaire in the past 1 month, then find the mean of the whole village.

HKI food frequency method: Whether or not a community has a vitamin A deficiency problem either of two threshold values

- \(\leq<4\) days per week for mean frequency of consumption of animal source of vitamin A
- \(\leq<6\) days per week for mean frequency of total consumption of animal and plant sources of vitamin A (weighted by the source)

#### Data Analyses

Descriptive statistics, students' t-test, analysis of variance were used to analyse the data.

### Results

None of the fathers and mothers from the study villages completed tertiary education. The percentages of fathers who completed primary and secondary schools were more than the mothers (primary school: 32.7% vs. 13.7%, \(p<0.05\); secondary school: 20% vs. 1.8%, \(p<0.05\), respectively); and could speak Thai language more than the mothers (32% vs. 15%, \(p<0.05\)). All families of the study boys and girls had income lower than the Thailand poverty line (US $ 1,000/year).

#### Vitamin A status of the study children

Table 2 showed mean and standard deviation of all the study biochemical parameters by village for boys and girls, respectively.

On average, 63% of children from Mae Hae Tai village, 1.5% of children from Mae Yot village and none of children from Mae Raek village had serum vitamin A 0.7 μmol/L (Table 3) which indicated vitamin A deficiency.

### Discussion

This paper reported results from a study of vitamin A status and malnutrition in a minority ethnic group of Karen hill tribe children aged 1-6 years in the northern part of Thailand. All children from the study villages came from families which had yearly income less than US$1,000 and low educational background. According to the government of Thailand, this income is below the poverty line. It is not surprising that in the future, these children will face several kinds of problems such as health conditions, illnesses and malnutrition.

All boys and only girls from Mae Raek village consumed vitamin A more than the Thai RDA but Girls from Mae Hae Tai village and Mae Yot village consumed vitamin A less than the Thai RDA. Both boys and girls from Mae Raek village and also girls from Mae Yot village consumed vitamin A more than the Thai RDA (Table 4).

### Village’s vitamin A status

Using SDA and HKI methods to assess vitamin A status of the villages to see whether vitamin A deficiency is a village's nutritional problem, it was found that all children from the three villages were at risk of vitamin A deficiency as shown in the Table 5.

### Table 5. Assessment of vitamin A status of the children (both sexes) by SDA and HKI methods whether vitamin A deficiency is a village’s problem or not

CI = consumption index, UPF = usual pattern of food consumption, SDA = Simplified Dietary assessment, HKI = Helen Keller International, HR: risk, MR: moderate risk, LR: low risk
Mae Hae Tai were found to have serum vitamin A deficiency. Indeed, SDA and HKI assessment methods found children of Mae Hae Tai village to be at high risk of vitamin A deficiency. In the Mae Reak village, on the other hand, the risk of vitamin A deficiency was assessed a low, and no children showed serum deficiency; risk in the Mae Yot village was medium, with only a very few children showing serum deficiency. This is consistent with dietary data which indicated that vitamin A levels consumed in Mae Reak village were above recommended daily allowances, whereas some age and gender groups in the other villages had quite low consumption levels, especially in the 4-6 year age group in Mae Hea Tai village.

These effects may be exacerbated in Mae Hae Tai children if fat consumption is low, since assimilation of beta carotene (precursor of vitamin A) is impossible if not enough fat is included in their diets. Earlier studies found that after supplementation with vegetable oil there was a 20% reduction in the number of children with either diarrhea or respiratory tract infection13, and a 13 percent reduction in abnormal conjunctival impression cytology (CIC, a biophysical assessment of vitamin A deficiency).14 Since supplementation with vegetable oil might increase absorption of fat-soluble vitamins, especially vitamin A,11 such an approach may be particularly useful in groups where consumption is marginal.

Study findings appeared to provide evidence that related to more nutritional stress on children in the Mae Hae Tai than that seen in children from other villages. Children in this village had highest risk of vitamin A deficiency.

In conclusion, in order to improve vitamin A status of the Karen children in Mae Chaem district, It was recommended that (1) an increased use of fat and oil, particularly in areas with high risk of vitamin A deficiency; (2) more general work with Karen communities on how children’s diets might be improved in a culturally acceptable manner, so as to bring vitamin A consumption closer to recommended allowance level.

Acknowledgement
This project was funded by the International Development Research Centre (IDRC), Canada, via the Ecosystem Approach to Human Health Program Initiative. We thank S Nimsakul, V Likit-ekaraj for their help and the Karen villagers in Mae Chaem district, Chiang Mai, Thailand, for their invaluable co-operation.

維生素 A 缺乏(VAD)是開發中世界最常見兒童失明的原因。據估計在維生素 A 缺乏的族群，給予適量的維生素 A 可以降低兒童 50%癲癇死亡率及 40%腹瀉性疾病死亡率。並可降低 23% 6-59 個月大的兒童總死亡率。本文報告的結果泰國北部 Karen 山區部落少數族群 1-6 歲兒童的維生素 A 營養狀況及營養不良的情形。泰國北部湄蔣縣的三個 Karen 部落(Mae Hae Tai, Mae Yot, Mae Raek) 1-6 歲兒童(N=158；83 名男孩，75 名女孩) 均納入研究。Karen 是泰國比較大的山區少數民族 (“山區部落”)。所有的兒童經過合格的醫生評估，並使用24 小時飲食回憶評估他們維生素 A 的攝取量。以泰國衛生部食物成分表為參考。結果與泰國的膳食建議攝取量作比較。泰國對 1-3 歲及 4-6 歲這兩個年齡層的兒童有不同的膳食建議攝取量，故在分析時也將兩組分開。使用“指尖取血”收集 300μL 的全血以測量血清中維生素 A。社區或是村落的維生素 A 營養狀況評估採用簡易膳食評估(SDA)方法及海倫凱勒國際基金會(HKI)食物頻率方法評估。採用描述性統計分析數據。參與研究的男孩及女孩的家庭收入均低於泰國的貧窮線(1,000 美元/年)。平均 63%Mae Hae Tai 村落的兒童及 1.5%Mae Yot 村落的兒童血清維生素 A<0.7μmol/L，即為 VAD，至於 Mae Paek 的兒童則沒有 VAD。所有的男孩與 Mae Paek 村落的女孩其維生素 A 摄取量超過泰國的 RDA，但是 Mae Hae Tai 村落及 Mae Yot 村落的女孩維生素 A 摄取量則低於泰國的 RDA。所有 Mae Paek 的男孩，與 Mae Yot 村落的女孩維生素 A 摄取量超過泰國的 RDA。以 SDA 及 HKI 方法評估維生素 A 營養狀況，探討 VAD 是否為村落中的營養問題，本研究發現這三個村落的兒童均有 VDA 的危險性。為了改善湄蔣縣 Karen 兒童的維生素 A 營養狀況，建議可以實行以下幾點方法: (1)增加油脂的使用，尤其是 VAD 高危險地區；(2)在 Karen 社區中，更一般性的工作應該是如何以文化可接受的方式去改善兒童飲食，以使維生素 A 的攝取量可以趨近建議量。
